

DM865 – Spring 2018  
Heuristics and Approximation Algorithms

# Construction Heuristics for Traveling Salesman Problem

Marco Chiarandini

Department of Mathematics & Computer Science  
University of Southern Denmark

# Outline

1. Combinatorial Optimization
2. Heuristic Methods
3. TSP
4. Code Speed Up

# Outline

1. Combinatorial Optimization
2. Heuristic Methods
3. TSP
4. Code Speed Up

# Aim of the Heuristic Part of the Course

To enable the student to solve **discrete optimization problems**  
that arise in practical applications

# Discrete and Combinatorial Optimization

- ▶ **Discrete optimization** emphasizes the difference to continuous optimization, solutions are described by **integer numbers** or **discrete structures**
- ▶ Combinatorial optimization is a subset of discrete optimization.
- ▶ Combinatorial optimization is the study of the ways **discrete structures** (eg, graphs) can be selected/arranged/combined: Finding an optimal object from a finite set of objects.
- ▶ Discrete/Combinatorial Optimization involves finding a way to efficiently allocate resources in mathematically formulated problems.

# Discrete Optimization Problems

## Discrete Optimization problems

They arise in many areas of

Computer Science, Artificial Intelligence, Operations Research....:

- ▶ allocating register memory
- ▶ planning, scheduling, timetabling
- ▶ Internet data packet routing
- ▶ protein structure prediction
- ▶ auction winner determination
- ▶ portfolio selection
- ▶ ...

# Discrete Optimization Problems

Simplified models are often used to formalize real life problems

- ▶ finding models of propositional formulae (SAT)
- ▶ finding variable assignment that satisfy constraints (CSP)
- ▶ partitioning graphs or digraphs
- ▶ partitioning, packing, covering sets
- ▶ finding shortest/cheapest round trips (TSP)
- ▶ coloring graphs (GCP)
- ▶ finding the order of arcs with minimal backward cost
- ▶ ...

## Example Problems

- ▶ They are chosen because conceptually concise, intended to illustrate the development, analysis and presentation of algorithms
- ▶ Although **real-world problems tend to have much more complex formulations**, these problems capture their essence

# Elements of Combinatorial Problems

Combinatorial problems are characterized by an **input**, i.e., a general description of **conditions** (or **constraints**) and **parameters**, and a **question** (or **task**, or **objective**) defining the properties of a **solution**.

They involve finding a **grouping**, **ordering**, or **assignment** of a **discrete**, **finite** set of objects that satisfies given conditions.

**Candidate solutions** are combinations of objects or **solution components** that need not satisfy all given conditions. They can be **partial solutions** or **complete solutions**.

**Feasible solutions** are candidate solutions that satisfy all given conditions.

**Optimal Solutions** are feasible solutions that maximize or minimize some criterion or objective function.

**Approximate solutions** are feasible candidate solutions that are not optimal but good in some sense.

# Traveling Salesman Problem

## Traveling Salesman Problem

Given: a weighted complete graph

Output: an Hamiltonian cycle of minimum total cost.

- ▶ <http://www.math.uwaterloo.ca/tsp/>
- ▶ “platform for the study of general methods that can be applied to a wide range of discrete optimization problems”
- ▶ arranging school bus routes to pick up the children in a school district.
- ▶ scheduling of service calls at cable firms
- ▶ delivery of meals to homebound persons
- ▶ scheduling of stacker cranes in warehouses
- ▶ scheduling of a machine to drill holes in a circuit board or other object
- ▶ routing of trucks for parcel post pickup

# General vs Instance

General problem vs problem instance:

General problem  $\Pi$ :

- ▶ Given *any* set of points  $X$  in a square, find a shortest Hamiltonian cycle
- ▶ *Solution*: Algorithm that finds shortest Hamiltonian cycle for any  $X$

Problem instantiation  $\pi = \Pi(I)$ :

- ▶ Given a *specific* set of points  $I$  in the square, find a shortest Hamiltonian cycle
- ▶ *Solution*: Shortest Hamiltonian cycle for  $I$

Problems can be formalized on sets of problem instances  $\mathcal{I}$  (*instance classes*)

# Traveling Salesman Problem

## Types of TSP instances:

- ▶ **Symmetric**: For all edges  $uv$  of the given graph  $G$ ,  $vu$  is also in  $G$ , and  $w_{uv} = w_{vu}$ .  
Otherwise: **asymmetric**.
- ▶ **Euclidean**: Vertices = points in an Euclidean space,  
weight function = Euclidean distance metric.
- ▶ **Geographic**: Vertices = points on a sphere,  
weight function = geographic (great circle) distance.

Alternatively, these features can become part of the general problem description and exploited in the development of the solution algorithm

# TSP: Benchmark Instances

## Instance classes

- ▶ Real-life applications (geographic, VLSI)
- ▶ Random Euclidean
- ▶ Random Clustered Euclidean
- ▶ Random Distance

Available at the TSPLIB (more than 100 instances upto 85.900 cities)  
and at the 8th DIMACS challenge

# TSP: Instance Examples

# Complete Algorithms and Lower Bounds

## Reference Results

- ▶ Branch & cut algorithms (Concorde: <http://www.math.uwaterloo.ca/tsp/concorde>)
  - ▶ cutting planes + branching
  - ▶ use LP-relaxation for lower bounding schemes
  - ▶ effective heuristics for upper bounds

| Solution times with Concorde |           |                 |
|------------------------------|-----------|-----------------|
| Instance                     | No. nodes | CPU time (secs) |
| att532                       | 7         | 109.52          |
| rat783                       | 1         | 37.88           |

2. Heuristic Methods
3. TSP
4. Code Speed Up

# Heuristics

Get inspired by approach to problem solving in human mind

[A. Newell and H.A. Simon. "Computer science as empirical inquiry: symbols and search." Communications of the ACM, ACM, 1976, 19(3)]

- ▶ effective rules without theoretical support
- ▶ trial and error

Applications:

- ▶ Optimization
- ▶ But also in Psychology, Economics, Management [Tversky, A.; Kahneman, D. (1974). "Judgment under uncertainty: Heuristics and biases". Science 185]

Basis on empirical evidence rather than mathematical logic. Getting things done in the given time. 16

# Outline

1. Combinatorial Optimization
2. Heuristic Methods
3. TSP
4. Code Speed Up

# Construction Heuristics

Construction heuristics specific for TSP

- ▶ Heuristics that Grow Fragments
  - ▶ Nearest neighborhood heuristics
  - ▶ Double-Ended Nearest Neighbor heuristic
  - ▶ Multiple Fragment heuristic (aka, greedy heuristic)
- ▶ Heuristics that Grow Tours
  - ▶ Nearest Addition
  - ▶ Farthest Addition
  - ▶ Random Addition
  - ▶ Clarke-Wright savings heuristic
  - ▶ Nearest Insertion
  - ▶ Farthest Insertion
  - ▶ Random Insertion
- ▶ Heuristics based on Trees
  - ▶ Minimum spanning tree heuristic
  - ▶ Christofides' heuristics
  - ▶ Fast recursive partitioning heuristic

## Construction Heuristics for TSP

**Figure 1.** The Nearest Neighbor heuristic.

- In geometric instances:  $NN < \frac{(\lceil \log N \rceil + 1)}{2} \cdot OPT$
- Double-Ended NN

# Nearest Neighbor Heuristic

```
Build(PtSet)
Perm[1]:=StartPt
DeletePt(Perm[1])
for i:=2 to N do
  | Perm[i]:=NN(Perm[i-1])
  | DeletePt(Perm[i])
```

# Data Structures

- ▶ Construction in  $O(n \log n)$  time and  $O(n)$  space
- ▶ Range search: reports the leaves from a split node.
- ▶ Delete(PointNum) amortized constant time
- ▶ NearestNeighbor(PointNum) bottom-up search  
visit nodes + compute distances  
 $A + BN^C$ ,  $A > 0, B < 0, -1 < C < 0$  (expected constant time) if no deletions happened and data uniform
- ▶ FixedRadiusNearestNeighbor(PointNum, Radius, function)
- ▶ BallSearch(PointNum, function) ball centered at point
- ▶ SetRadius(PointNum, float Radius)
- ▶ SphereOfInfluence(PointNum, float Radius) ball centered at point with given radius

## Construction Heuristics for TSP

**Figure 5.** The Multiple Fragment heuristic.

►  $O(\sqrt{N})$  approximation

- ▶ Array Degree num. of tour edges
- ▶ K-*d* tree for nearest neighbor searching (only eligible nodes)
- ▶ Array NNLink containing index to nearest neighbor of *i* not in the fragment of *i*
- ▶ Priority queue (heap) with nearest neighbor links
- ▶ Array Tail link to the other tail of current fragments.

# Important Elements

- ▶ Exploit the locality inherent in the problem to solve it (NN search, Fixed-radius search, ball search)
- ▶ Search time modelled by a function  $A + BN^C$
- ▶ Number of searches
- ▶ Priority queue of links to nearest neighbors

## Addition Heuristics

**Figure 8.** The Nearest Addition heuristic.

Tour maintained as a doubly-linked list

## Addition Heuristics

**Figure 11.** The Farthest Addition heuristic.

## Addition Heuristics

**Figure 14.** The Random Addition heuristic.

# Insertion Heuristics

Motivation:

## Theorem

$Y$  not yet in tour

$C$  nearest neighbor of  $Y$

$D$  neighbor of  $C$  in tour that minimize  $C(Y, CD)$

The tour edges with minimal expansion is:

- ▶ the nearest neighbor edge  $CD$
- ▶ the edge  $AB$  such that  $A$  is in  $\text{NNBall}(Y, 1.5 \cdot e_{\min})$ ,  $e_{\min}$  shorest edge from  $Y$
- ▶ the edge  $AB$  such that  $Y$  is in  $\text{SphereOfInfluence}(A, 1.5 \cdot e_{\max})$ ,  $e_{\max}$  longest edge from  $A$  scale 1.5

Proof:  $C(Y, CD) \leq 2D(Y, C)$

## Construction Heuristics for TSP

**Figure 18.** The Minimum Spanning Tree heuristic.

$$MST \leq 2 \cdot OPT$$

## Construction Heuristics for TSP

**Figure 19.** Christofides' heuristic.

$$CH \leq \frac{3}{2} \cdot OPT \text{ tight and best known}$$

# Outline

1. Combinatorial Optimization
2. Heuristic Methods
3. TSP
4. Code Speed Up

# Where do speedups come from?

Where can maximum speedup be achieved?  
How much speedup should you expect?

# Code Tuning

- ▶ Caution: proceed carefully! Let the optimizing compiler do its work!
  - ▶ optimizing flags
  - ▶ just-in-time-compilation: it converts code at runtime prior to executing it natively, for example bytecode into native machine code. (module numba [https://www.ibm.com/developerworks/community/blogs/jfp/entry/Fast\\_Computation\\_of\\_AUC\\_ROC\\_score?lang=en](https://www.ibm.com/developerworks/community/blogs/jfp/entry/Fast_Computation_of_AUC_ROC_score?lang=en))
- ▶ Caching, memoization (`@functools.lru_cache(None)`)
- ▶ Profiling (module `cProfile`)

- ▶ Expression Rules: Recode for smaller instruction counts.
- ▶ Loop and procedure rules: Recode to avoid loop or procedure call overhead.
- ▶ Hidden costs of high-level languages
- ▶ String comparisons: proportional to length of the string, not constant
- ▶ Object construction / de-allocation: very expensive
- ▶ Matrix access: row-major order  $\neq$  column-major order
- ▶ Exploit algebraic identities
- ▶ Avoid unnecessary computations inside the loops

# Where Speedups Come From?

McGeoch reports conventional wisdom, based on studies in the literature.

- ▶ Concurrency is tricky: bad -7x to good 500x
- ▶ Classic algorithms: to 1trillion and beyond
- ▶ Data-aware: up to 100x
- ▶ Memory-aware: up to 20x
- ▶ Algorithm tricks: up to 200x
- ▶ Code tuning: up to 10x
- ▶ Change platforms: up to 10x
